

Porous photovoltaic panels

Overview

A group of researchers from Iran's University of Tehran has developed a porous silicon-carbide (SiC) ceramic that, especially if used in combination with a phase change material (PCM), can reduce solar module temperature and increase its efficiency. This study investigates the potential of low-cost, naturally available porous materials (PoMs), gravel, marble, flint, and sandstone, as thermal management for photovoltaic (PV) panels. Experiments were conducted in a controlled environment at a solar energy laboratory, where variables such as. Porous organic polymers (POPs) have attracted significant attention for solar energy applications due to their high surface areas, chemical stability, and tunable structures. In hyper-arid regions, elevated operating temperatures significantly reduce panel efficiency.
